Selenium plays a fundamental role in several major metabolic pathways of human and animals, but high daily dose (above 400ug per day) of selenium can result in severe illness (Li, 2015). Fe-based nanoparticles (FNPs) based process, combining adsorption, catalyze and reduction, possesses great potential for in situ selenium removal with advantage of its low cost and toxicity (Tang 2014). Supported FNPs show good stability and transport properties while still possess high reactivity of FNPs, which recently have attracted much attention in practical environmental remediation (Sheng 2015).

One step pyrolysis of Fe preloaded biomass is a fast and robust way to produce biochar supported FNPs. Sawdust, an abundant forestry residue, has been proved to be an ideal precursor to synthesis biochar supported FNPs because of its low ash content.

This work presents a comparative study of biochar supported magnetite nanoparticles (BC-nFe₃O₄) and zero valent iron nanoparticles (BC-nFe⁰) for selenate removal for the first time. The biochar supported nanoparticles were produced from one step pyrolysis of FeCl₃ pretreated pine wood sawdust, and the iron phase was controlled by pyrolysis temperature.

XRD patterns (Fig. 1) showed that the Fe₃O₄ nanoparticles were formed at 500 °C that these particles were reduced to zero valent iron nanoparticles at 700 °C. SEM images showed that the size of the nanoparticles were about 10-100nm in diameter and were anchored separately in the biochar matrix.

Batch experiments showed that the removal efficiency of selenate and sulfate by BC-nFe₃O₄ and BC-nFe⁰ was pH dependent, as shown in Fig. 2. BC-nFe₃O₄ was more effective for selenate removal under pH above 4 while BC-nFe⁰ was more effective under pH below 4.

The strong influence of ion strength on removal efficiency of both BC-nFe₃O₄ and BC-nFe⁰ especially under neutral to alkaline pH conditions implies an outer sphere complexation of selenate with the material surface.
The XPS characterization of the reacted materials showed that the removal of selenate by BC-nFe₃O₄ was mainly through adsorption while that by BC-nFe⁰ was mainly through reduction.

Binary removal of selenate and sulfate showed that the adsorption by BC-nFe₃O₄ had little selectivity toward selenate while BC-nFe⁰ preferred to react with selenate through reduction especially under acidic conditions.
