# GHG emissions from landfills

Simplified Landfill Methane Mass Balance

$$\text{Methane (CH}_4\text{) produced (mass/time)} = \Sigma(\text{CH}_4 \text{ recovered} + \text{CH}_4 \text{ emitted} + \text{CH}_4 \text{ oxidized})$$

# Solid waste landfilling technologies

---

## ❖ **Dump**

The dump refers to a landfill where many different kinds of waste are disposed of with little or no benefit of an engineering plant. The waste is not compacted, no measures exist to prevent gas and leachate emissions to the environment, and the waste is not covered.

## ❖ **Conventional landfill**

A conventional landfill, as typically defined, is a landfill that implements technical measures to collect and manage the leachate and gas generated (as also foreseen in the Landfill Directive).

## ❖ **Engineered landfills with energy recovery**

In addition to the technical measures implemented in conventional landfills, these technologies adopt active measures to enhance the waste degradation process, in order to make it faster and more efficient.

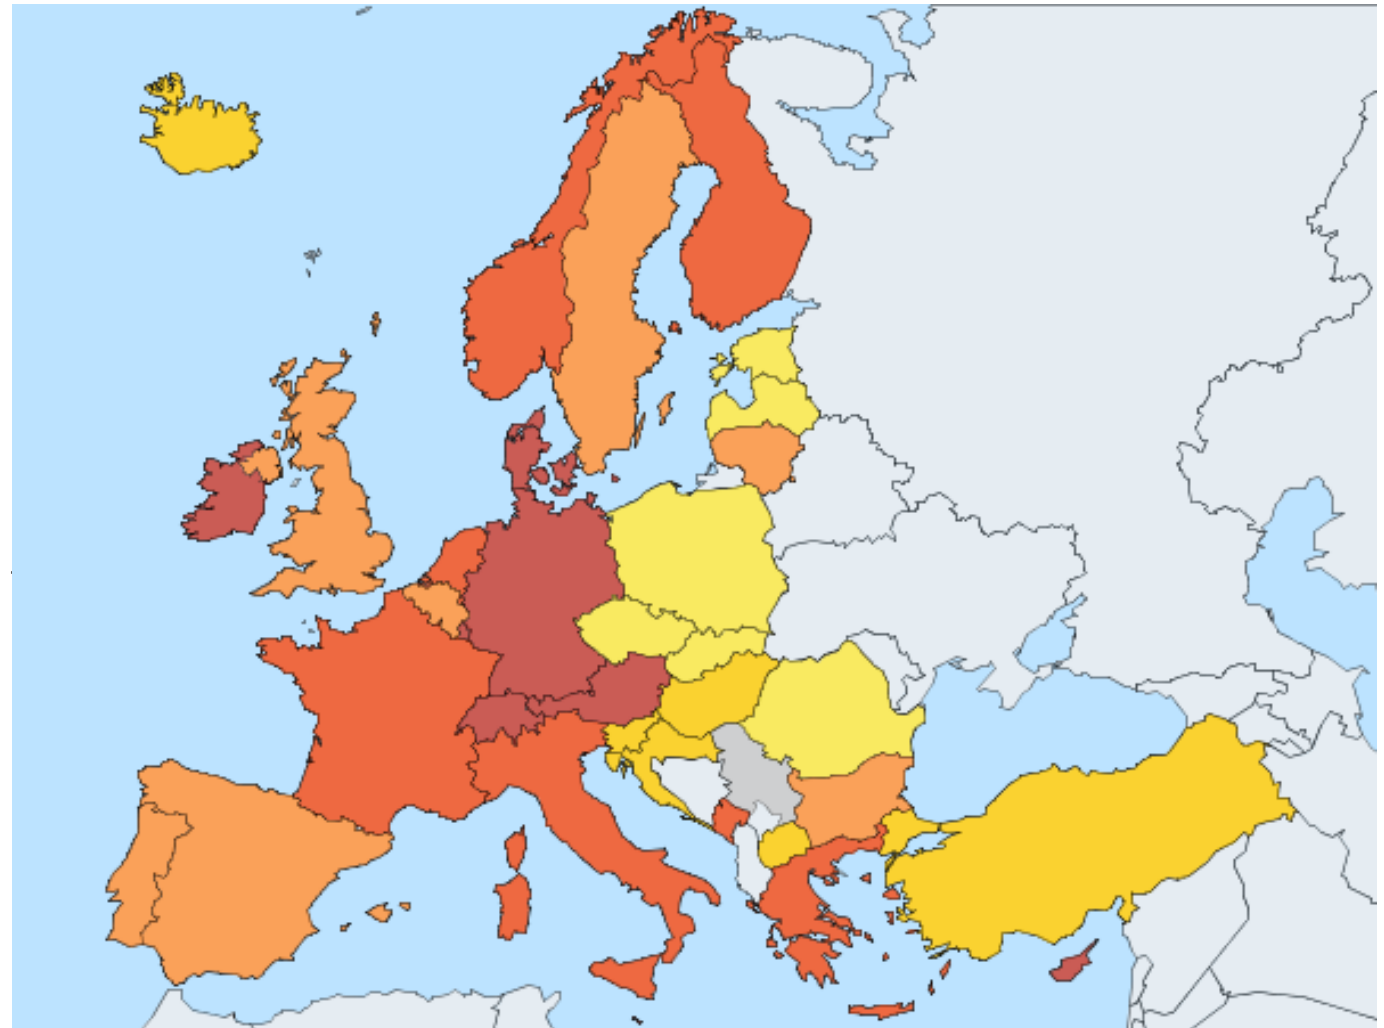

## ❖ **Engineered landfills for low organic waste**

These landfills are destined for the disposal of residual waste. Similar to engineered landfills, these landfills adopt technical measures to collect and treat the generated leachate.

# Waste management in the EU-28 (2013)

# The EU legislation: Waste Framework Directive 2008/98/EC

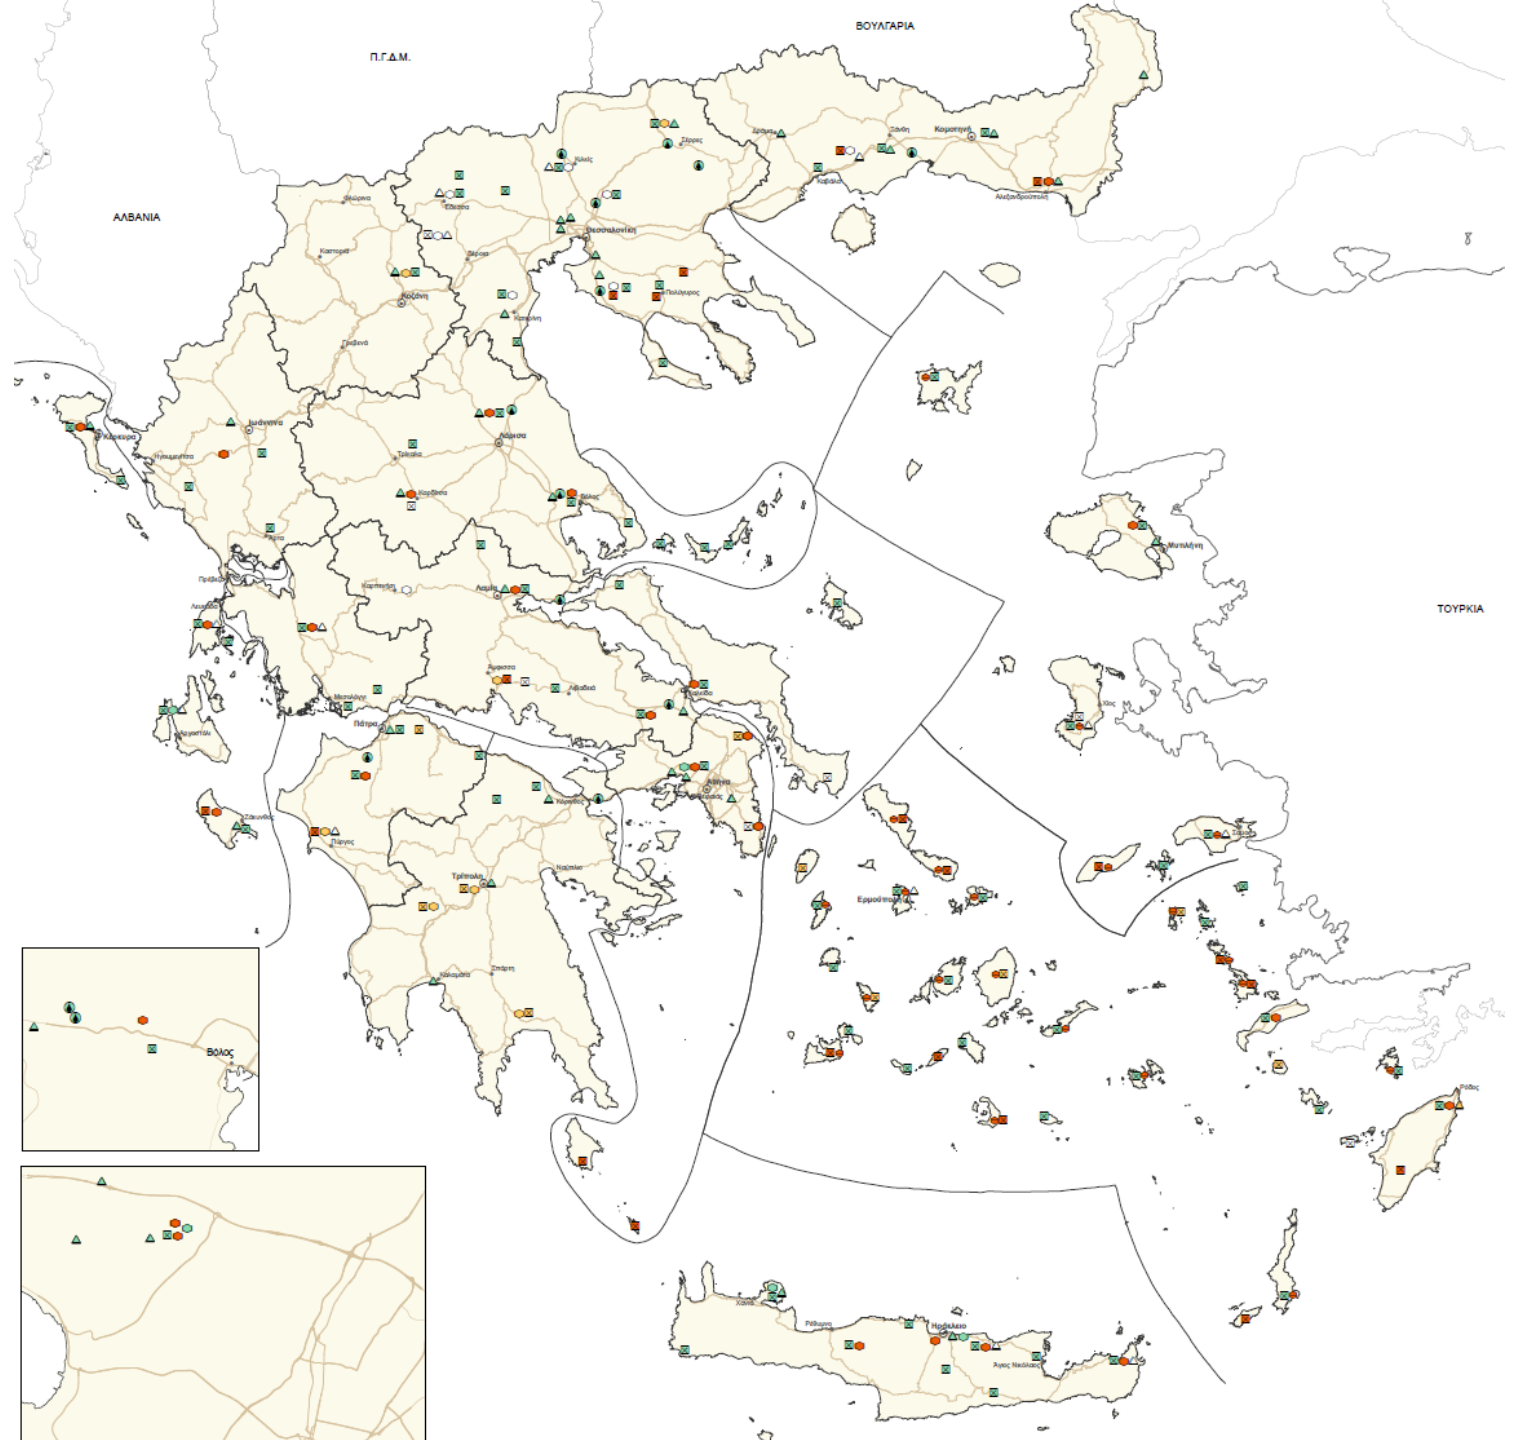

# Average net GHG emissions from different types of waste management methods

# MSW management facilities in Greece

- 29 Material Recovery Facilities
- 4 Mechanical Biological Treatment Plants
- 79 Sanitary landfills (75 in operation)
- 39 Dumps in operation

# National Waste Management Plan in Greece

---

The National Waste Management Plan (NWMP) sets a number of ambitious targets for waste management by 2020:

- Preparing for re-use and recycling with separate collection of recyclable and biowaste of at least 50% w/w of MSW
- Reduction of BMW going to landfills to 35% w/w (compared to 1997 levels)
- Reduction of total waste disposal of MSW to <30% w/w
- Separate collection of 40% w/w of BMW
- Preparing for re-use and recycling of 65% w/w of at least paper, glass, metal and plastic
- Recovery of 60% and recycling 55-80% w/w of packaging waste

# GHG emissions for different landfill scenarios

# Concluding remarks

- Although landfill disposal of MSW is considered the least preferred option, there is great potential for reducing its carbon footprint
- Landfilling is unavoidable, as with any other waste management option, there will always be an amount of residual waste that will need to be disposed of
- Waste, even when disposed of in landfills, holds a significant value that may still be exploited
- The amount of biodegradable waste disposed of in landfills must be reduced to avoid methane generation in landfills
- In all cases, standards must be followed for reducing landfill methane emissions by capture and combustion of landfill gas with or - if this is not possible - without energy recovery
- Achieving the targets set in the National Waste Management Plan for 2020, is expected to substantially reduce landfill emissions in Greece

**Thank you for your  
time and your  
attention!!**
